Optimisation for Data Science

Constrained optimization problem

We consider the constrained optimization problem (\mathcal{P}) :

$$\min_{x \in \mathcal{D}} f(x)$$

- where $f : \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ is a convex **objective function**
- \mathcal{D} is the **domain** which we assume is a **convex set**.

→ Assuming f is smooth how would you solve this?

→ Give me examples in machine learning of such a problem.

Constrained optimization problem

$$\min_{x \in \mathcal{D}} f(x)$$

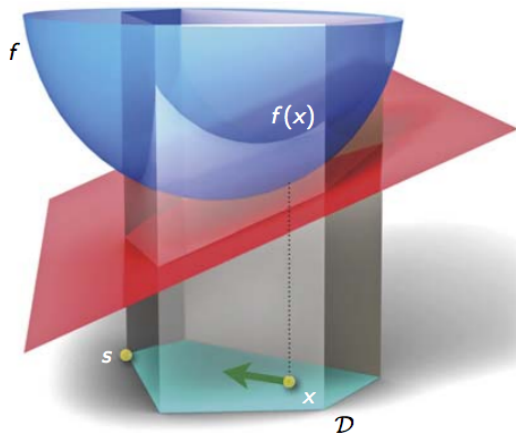

Image courtesy of Martin Jaggi (cf. [Jag13]).

Many applications

- network flows / transportation problems
- greedy selection and sparse optimization
- with wavelets (infinite-dimensional space)
- structured sparsity and structured prediction
- low-rank matrix factorizations, collaborative filtering
- total-variation-norm for image denoising
- submodular optimization
- boosting

Application:

Low-Rank Matrix Completion for collaborative filtering

Let $Y \in \mathbb{R}^{n \times m}$ be a partially observed data matrix.

Remark: Think of n as users and m as products and Y contains grades from 1 to 5.

Ω denotes the entries of Y that are observed ($|\Omega| \ll n \times m$)

We want to solve:

$$\min_{X \in \mathbb{R}^{n \times m}} \sum_{(i,j) \in \Omega} (Y_{ij} - X_{ij})^2$$

$$\text{s.t. } \|X\|_N \leq r.$$

where $\|X\|_N$ is the nuclear norm (sum of singular values).

$\|\cdot\|_N$ is a convex approximation of the rank.

Remark: $\mathcal{C} = \{X \in \mathbb{R}^{n \times m} \text{ s.t. } \|X\|_N \leq r\}$ convex.

LMO and linearization

- The Linear Minimization Oracle

$$\text{LMO}_{\mathcal{D}}(d) = \arg \min_{s \in \mathcal{D}} \langle d, s \rangle$$

- Linearization

$$\min_{s \in \mathcal{D}} f(x) + \langle \nabla f(x), s - x \rangle$$

- Idea:

$$x^{k+1} \approx \cancel{\arg \min_{s \in \mathcal{D}}} \text{LMO}_{\mathcal{D}}(\nabla f(x^k))$$

- Step depends on domain \mathcal{D} and $\nabla f(x^k)$, hence the name **conditional gradient**.

Convergence

- Marguerite Frank and Philip Wolfe showed in [FW56] that:

$$f(x^k) - f(x^*) \leq \mathcal{O}(1/k)$$

- Provided that:
 - f is smooth and convex
 - \mathcal{D} is bounded and convex

Remark: Same rates as projected gradient method but with simpler iterations. It is a projection free algorithm.

Frank-Wolfe / Conditional Gradient algorithm

```
1:  $x^0 \in \mathbf{D}$   
2: for  $k = 0$  to  $n$  do  
3:    $s = \text{LMO}_{\mathcal{D}}(\nabla f(x^k))$   
4:    $\gamma = \frac{2}{k+2}$   
5:    $x^{k+1} = (1 - \gamma)x^k + \gamma s$   
6: end for  
7: return  $x^{n+1}$ 
```

Frank-Wolfe / Conditional Gradient algorithm

```
1:  $x^0 \in \mathbf{D}$   
2: for  $k = 0$  to  $n$  do  
3:    $s = \text{LMO}_{\mathcal{D}}(\nabla f(x^k))$   
4:    $\gamma = \frac{2}{k+2}$   
5:    $x^{k+1} = (1 - \gamma)x^k + \gamma s$   
6: end for  
7: return  $x^{n+1}$ 
```

With line search:

$$\gamma = \arg \min_{\gamma \in [0,1]} f((1 - \gamma)x^k + \gamma s)$$

Convergence proof

Theorem

For each $k \geq 1$, the iterates x^k of the Frank-Wolfe algorithm satisfy

$$f(x^k) - f(x^*) \leq \frac{2C_f}{k+2} .$$

Remark: C_f defined on next slide.

Convergence proof

PROOF. Let C_f a “curvature” constant such that:

$$f(y) \leq f(x) + \underbrace{\gamma \langle s - x, \nabla f(x) \rangle}_{-\gamma g(x)} + \frac{\gamma^2}{2} C_f$$

for all $x, s \in \mathcal{D}$, $y = x + \gamma(s - x)$, $\gamma \in [0, 1]$.

Writing $h(x^k) = f(x^k) - f(x^*)$ for the error on objective, we have:

$$\begin{aligned} h(x^{k+1}) &\leq h(x^k) - \gamma g(x^k) + \frac{\gamma^2}{2} C_f && \text{(Definition of } C_f) \\ &\leq h(x^k) - \gamma h(x^k) + \frac{\gamma^2}{2} C_f && (h \leq g \text{ by convexity \& prop. of } s) \\ &= (1 - \gamma)h(x^k) + \frac{\gamma^2}{2} C_f. \end{aligned}$$

From here, the decrease rate follows from a simple lemma.

Convergence proof

Lemma

Suppose a sequence of numbers $(h_k)_k$ satisfies

$$h_{k+1} \leq (1 - \gamma^k)h_k + (\gamma^k)^2 C$$

for $\gamma^k = \frac{2}{k+1}$, and $k = 0, 1, \dots$, and a constant C . Then

$$h_k \leq \frac{4C}{k+2}, \quad k = 0, 1, \dots$$

PROOF. Trivial by induction.

Remark: [LJJ13] shows a linear/exponential convergence if f strongly convex and use line-search. It is like projected gradient descent but without projection!

Curvature constant vs. L-Lipschitz gradient

The curvature constant C_f is defined by:

$$C_f = \sup_{\substack{x, s \in \mathcal{D}, \\ \gamma \in [0, 1] \\ y = x + \gamma(s - x)}} \frac{2}{\gamma^2} (f(y) - f(x) - \langle y - x, \nabla f(x) \rangle) .$$

Lemma

Let f be a convex and differentiable function with its gradient ∇f being Lipschitz-continuous w.r.t. some norm $\|\cdot\|$ over the domain \mathcal{D} with Lipschitz-constant $L_{\|\cdot\|} > 0$. Then:

$$C_f \leq \text{diam}_{\|\cdot\|}(\mathcal{D})^2 L_{\|\cdot\|} .$$

PROOF. Give it a try!

Optimality certificate (almost for free)

We solve:

$$\min_{x \in \mathcal{D}} f(x)$$

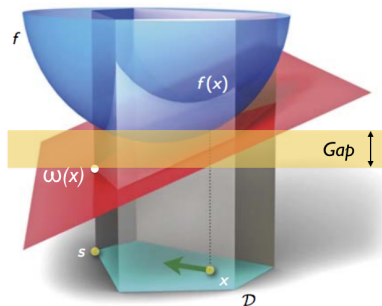

Let:

$$\omega(x) = \min_{s \in \mathcal{D}} f(x) + \langle \nabla f(x), s - x \rangle$$

Lemma (Weak duality)

$$\omega(x) \leq f(x^*) \leq f(x)$$

So if $f(x) - \omega(x) \leq \epsilon$, x is an ϵ -solution.

Special case of Atomic Sets

If

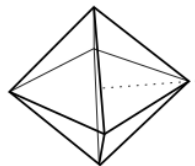

$$\mathcal{D} = \text{conv}(\mathcal{A})$$

where \mathcal{A} is a set (possibly infinite) of atoms/vectors.

Then we have that for every FW step $s \in \mathcal{A}$.

Example of ℓ_1 ball:

$$\mathcal{D} = \text{conv}(\{e_i | i \in [n]\} \cup \{-e_i | i \in [n]\})$$

So $s = \text{LMO}_{\mathcal{D}}(\nabla f(x^k)) \in \{e_i | i \in [n]\} \cup \{-e_i | i \in [n]\}$.

Let's practice
