

Exercise List: Proving convergence of the (Stochastic) Gradient Descent Method for the Least Squares Problem.

Robert M. Gower.

October 3, 2017

1 Introduction

This is an exercise in proving the convergence of iterative optimization methods. We will take a simple case study: solving the linear least squares problem, and prove the linear convergence of the gradient descent method and a variant of the stochastic gradient descent (SGD) method with importance sampling. This variant of SGD is also known as the randomized Kaczmarz method and the linear convergence we prove in **Exe.2** was first established in [3].

First we introduce some necessary notation.

Notation: For every $x, y \in \mathbb{R}^n$ let $\langle x, y \rangle \stackrel{\text{def}}{=} x^\top y$ and let $\|x\|_2 = \sqrt{\langle x, x \rangle}$. Let $\sigma_{\min}(A)$ and $\sigma_{\max}(A)$ be the smallest and largest singular values of A defined by

$$\sigma_{\min}(A) \stackrel{\text{def}}{=} \min_{x \in \mathbb{R}^n, x \neq 0} \frac{\|Ax\|_2}{\|x\|_2} \quad \text{and} \quad \sigma_{\max}(A) \stackrel{\text{def}}{=} \max_{x \in \mathbb{R}^n, x \neq 0} \frac{\|Ax\|_2}{\|x\|_2}. \quad (1)$$

Thus clearly

$$\frac{\|Ax\|_2^2}{\|x\|_2^2} \leq \sigma_{\max}(A)^2, \quad \forall x \in \mathbb{R}^n. \quad (2)$$

Let $\|A\|_F^2 \stackrel{\text{def}}{=} \text{Tr}(A^\top A)$ denote the Frobenius norm of A . Finally, a result you will need, is that for every symmetric positive semi-definite matrix G the $L2$ induced matrix norm can be equivalently defined by

$$\sigma_{\max}(G) = \max_{x \in \mathbb{R}^n, x \neq 0} \frac{\langle Gx, x \rangle_2}{\|x\|_2^2} = \max_{x \in \mathbb{R}^n, x \neq 0} \frac{\|Gx\|_2}{\|x\|_2}. \quad (3)$$

2 The Linear Least Squares Problem

Now consider the problem of solving the linear system

$$Ax = b, \tag{4}$$

where $A \in \mathbb{R}^{m \times n}$ and $b \in \mathbb{R}^m$. We assume that there exists a solution to (4). We also assume that $n \leq m$ and that A has full column rank so that there is a unique solution $x^* \in \mathbb{R}^n$ to (4). We can recast (4) as the following *Least Squares* optimization problem

$$x^* = \arg \min_{x \in \mathbb{R}^n} \left(\frac{1}{2} \|Ax - b\|_2^2 \stackrel{\text{def}}{=} f(x) \right). \tag{5}$$

3 Exercises

Ex. 1 — Consider the Gradient descent method

$$x^{t+1} = x^t - \alpha \nabla f(x^t), \tag{6}$$

where

$$\alpha = \frac{1}{\sigma_{\max}(A)^2}, \tag{7}$$

is a fixed stepsize.

Part I

Show or convince yourself that

$$\sigma_{\max}(I - \alpha A^\top A) = 1 - \alpha \sigma_{\min}(A)^2 = 1 - \frac{\sigma_{\min}(A)^2}{\sigma_{\max}(A)^2}. \tag{8}$$

Part II

Calculate the gradient $\nabla f(x)$ of (5) and re-write the iterates (6) with this gradient.

Part III

Show that the iterates (6) converge to x^* according to

$$\|x^{t+1} - x^*\|_2 \leq \left(1 - \frac{\sigma_{\min}(A)^2}{\sigma_{\max}(A)^2} \right) \|x^t - x^*\|_2,$$

for all t .

Hint 1: Subtract x^* from both sides of (6) and use the results from the previous two exercises.

Hint 2: Remember that $b = Ax^*$!

Answer (Ex. I) — First note that

$$\begin{aligned}
\langle (I - \alpha A^\top A)x, x \rangle &= \|x\|_2^2 - \alpha \|Ax\|_2^2 \\
&\stackrel{(7)}{\geq} \|x\|_2^2 - \frac{\|Ax\|_2^2}{\sigma_{\max}(A)^2} \\
&\stackrel{(2)}{\geq} \|x\|_2^2 - \frac{\sigma_{\max}(A)^2 \|x\|_2^2}{\sigma_{\max}(A)^2} = 0,
\end{aligned}$$

thus the matrix $(I - \alpha A^\top A)$ is positive semi-definite and only has non-negative eigenvalues. Furthermore

$$\frac{\langle (I - \alpha A^\top A)x, x \rangle}{\|x\|_2^2} = 1 - \alpha \frac{\langle A^\top Ax, x \rangle}{\|x\|_2^2}. \quad (9)$$

Since $(I - \alpha A^\top A)$ is symmetric positive semi-definite we can use (3) to calculate the induced norm, thus we have

$$\begin{aligned}
\sigma_{\max}(I - \alpha A^\top A) &\stackrel{(3)+(9)}{=} \max_{x \in \mathbb{R}^n} \left(1 - \alpha \frac{\langle A^\top Ax, x \rangle}{\|x\|_2^2} \right) \\
&= 1 - \alpha \min_{x \in \mathbb{R}^n} \frac{\langle A^\top Ax, x \rangle}{\|x\|_2^2} \\
&= 1 - \alpha \sigma_{\min}(A)^2.
\end{aligned}$$

Answer (Ex. II) — Differentiating we have

$$\nabla f(x) = A^\top (Ax - b) = A^\top A(x - x^*),$$

where the last equality follows since $Ax^* = b$. Consequently the gradient descent method (6) can be written as

$$x^{t+1} = x^t - \alpha A^\top A(x^t - x^*). \quad (10)$$

Answer (Ex. III) — Subtracting x^* from both sides of (10) gives

$$x^{t+1} - x^* = x^t - x^* - \alpha A^\top A(x^t - x^*) = (I - \alpha A^\top A)(x^t - x^*).$$

Taking norm in the above gives

$$\begin{aligned}
\|x^{t+1} - x^*\|_2 &\stackrel{(2)}{\leq} \sigma_{\max}(I - \alpha A^\top A) \|x^t - x^*\|_2 \\
&\stackrel{(8)}{=} (1 - \alpha \sigma_{\min}(A)^2) \|x^t - x^*\|_2.
\end{aligned}$$

In particular for $\alpha = \frac{1}{\sigma_{\max}(A)^2}$ the above shows that

$$\|x^{t+1} - x^*\|_2 \leq \left(1 - \frac{\sigma_{\min}(A)^2}{\sigma_{\max}(A)^2}\right) \|x^t - x^*\|_2.$$

Ex. 2 — The least squares problem (5) can be re-written as

$$\min_x \frac{1}{2} \|Ax - b\|_2^2 = \min_x \frac{1}{2} \sum_{i=1}^m (A_{i:}x - b_i)^2 \stackrel{\text{def}}{=} \min_x \frac{1}{2} \sum_{i=1}^m f_i(x) \quad (11)$$

where $f_i(x) = (A_{i:}x - b_i)^2$, $A_{i:}$ denotes the i th row of A and b_i denotes the i th element of b . Given this *sum of terms* structure in (11) we can implement the stochastic gradient method as follows. From a given $x^0 \in \mathbb{R}^n$, consider the iterates

$$x^{t+1} = x^t - \alpha_j \nabla f_j(x^t), \quad (12)$$

where

$$\alpha_j = \frac{1}{\|A_{j:}\|_2^2}, \quad (13)$$

and j is a random index chosen from $\{1, \dots, m\}$ such that for every $i \in \{1, \dots, m\}$ the probability that $j = i$ is given by $\frac{\|A_{i:}\|_2^2}{\|A\|_F^2}$. In other words, $\mathbb{P}(j = i) = \frac{\|A_{i:}\|_2^2}{\|A\|_F^2}$ for all $i \in \{1, \dots, m\}$.

Part I

Show that

$$P_j \stackrel{\text{def}}{=} \alpha_j A_{j:}^\top A_{j:} = \frac{A_{j:}^\top A_{j:}}{\|A_{j:}\|_2^2}, \quad (14)$$

is a projection operator which projects orthogonally onto **Range**($A_{j:}$). In other words, show that

$$P_j P_j = P_j \quad \text{and} \quad (I - P_j)(I - P_j) = I - P_j. \quad (15)$$

Furthermore, verify that

$$\mathbb{E}[P_j] = \sum_{i=1}^m \mathbb{P}(j = i) P_i = \frac{A^\top A}{\|A\|_F^2}. \quad (16)$$

Part II

Using analogous techniques from the previous exercise, show that the iterates (12) converge according to

$$\mathbb{E} [\|x^{t+1} - x^*\|_2^2] \leq \left(1 - \frac{\sigma_{\min}(A)^2}{\|A\|_F^2}\right) \mathbb{E} [\|x^t - x^*\|_2^2]. \quad (17)$$

This is an amazing and recent result [3], since **it shows that SGD converges exponentially fast despite the fact that the iterates (12) only require access to a single row of A at a time!** This result can be extended to any matrix A , including rank deficient matrices. Indeed, so long as there exists a solution to (4), the iterates (12) converge to the solution of least norm and at rate of $\left(1 - \frac{\sigma_{\min}^+(A)^2}{\|A\|_F^2}\right)$ where $\sigma_{\min}^+(A)$ is the smallest nonzero singular value of A [1]. **Thus the assumption that A has full column rank is not necessary.** These results have also been extended to a general class of methods [2].

Part III

When is this stochastic gradient method (12) *faster* than the gradient descent method (6)? Note that the **each iteration of SGD costs $O(n)$** floating point operations while an iteration of the GD method costs $O(nm)$ floating point operations. What happens if m is very big? What if $\|A\|_F^2$ is very large? Discuss this.

Answer (Ex. I) — Verify by most all claim by direct computation. For instances

$$\mathbb{E} [P_j] = \sum_{i=1}^m \mathbb{P}(j = i) P_i = \sum_{i=1}^m \frac{\|A_{i:}\|_2^2}{\|A\|_F^2} \frac{A_{i:}^\top A_{i:}}{\|A_{i:}\|_2^2} = \sum_{i=1}^m \frac{A_{i:}^\top A_{i:}}{\|A\|_F^2} = \frac{A^\top A}{\|A\|_F^2}.$$

Answer (Ex. II) — First note that

$$\nabla f_j(x^t) = A_{j:}^\top (A_{j:} x - b_j) = A_{j:}^\top A_{j:} (x - x^*).$$

Using the above and subtracting x^* from both sides of (12) we have

$$\begin{aligned} x^{t+1} - x^* &= x^t - x^* - \alpha_j A_{j:}^\top A_{j:} (x^t - x^*) \\ &\stackrel{(13)}{=} \left(I - \frac{A_{j:}^\top A_{j:}}{\|A_{j:}\|_2^2} \right) (x^t - x^*). \end{aligned}$$

Taking norm squared in the above we have that

$$\begin{aligned} \|x^{t+1} - x^*\|_2^2 &= \left\| \left(I - \frac{A_{j:}^\top A_{j:}}{\|A_{j:}\|_2^2} \right) (x^t - x^*) \right\|_2^2 \\ &\stackrel{(15)}{=} \left\langle \left(I - \frac{A_{j:}^\top A_{j:}}{\|A_{j:}\|_2^2} \right) (x^t - x^*), x^t - x^* \right\rangle \\ &= \|x^t - x^*\|_2^2 - \left\langle \frac{A_{j:}^\top A_{j:}}{\|A_{j:}\|_2^2} (x^t - x^*), x^t - x^* \right\rangle. \end{aligned}$$

Taking expectation **conditioned on x^t** in the above gives

$$\begin{aligned}
\mathbb{E} [\|x^{t+1} - x^*\|_2^2 \mid x^t] &= \|x^t - x^*\|_2^2 - \left\langle \mathbb{E} \left[\frac{A_{j:}^\top A_{j:}}{\|A_{j:}\|_2^2} \right] (x^t - x^*), x^t - x^* \right\rangle \\
&\stackrel{(16)}{=} \|x^t - x^*\|_2^2 - \frac{1}{\|A\|_F^2} \left\langle A^\top A (x^t - x^*), x^t - x^* \right\rangle \\
&\stackrel{(1)}{\leq} \|x^t - x^*\|_2^2 - \frac{\sigma_{\min}(A)^2}{\|A\|_F^2} \|x^t - x^*\|_2^2 \\
&= \left(1 - \frac{\sigma_{\min}(A)^2}{\|A\|_F^2} \right) \|x^t - x^*\|_2^2.
\end{aligned}$$

It remains to take expectation in the above. E (E (X_{t+1} - X* | X_t))

Answer (Ex. III) — ...

prove that $\|A\|_F^2 = \sum(\sigma_i^2)$
